Correctness

ADS

```
INSERTION-SORT (A, n)

for j = 2 to n

key = A[j]

// Insert A[j] into the sorted sequence A[1..j-1].

i = j-1

while i > 0 and A[i] > key

A[i+1] = A[i]

i = i-1

A[i+1] = key
```

Loop invariant: is a property of a program loop that is true before (and after) each iteration

Example of loop invariant: at the start of each iteration of the for loop, the subarray A[1...j-1] consists of elements originally in A[1...j-1], but in sorted order.

Spring 2020

Running Time

- ► The running time depends on the input: an already sorted sequence is easier to sort
- ► Parameterize running time by the size of the input: short sequences are easier to sort than long ones
- Generally, we seek upper bounds on the running time: we would like to have a guarantee

Types of Analyses

- ► Worst case (usually) T(n) = maximum time of algorithm on any input of size n
- Average case (sometimes)
 T(n) = expected time of algorithm over all inputs of size n
 (Need assumption of statistical distribution of inputs)
- Best case (almost never)
 Does not make much sense, e.g., we can start with the solution

Asymptotic Analysis

- ▶ What is Insertion Sort's worst-case time?
 - ▶ It depends on the speed of our computer: relative speed (on the same machine), absolute speed (on different machines)
- ► Idea
 - ► Ignore machine-dependent constants
 - ▶ Look at growth of T(n) as $n \to \infty$

Asymptotically Tight Bound: Θ-Notation

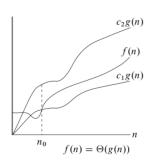

For a given asymptotically non-negative function g(n), we define $\Theta(g(n)) = \{f(n) | \exists \text{ positive constants } c_1, c_2 \text{ and } n_0, \text{ such that } 0 \le c_1 g(n) \le f(n) \le c_2 g(n), \forall n \ge n_0 \}$

We often write $f(n) = \Theta(g(n))$ (not an equation, also not an assignment) instead of $f(n) \in \Theta(g(n))$. The same is meant by both

notations. Example:

$$f(n) = 3n^3 + 90n^2 - 5n + 6046$$

$$3n^3 + 90n^2 - 5n + 6046 = \Theta(n^3)$$

ADS Spring 2020 6 / 23

Example

$$c_1 n^3 \le 3n^3 + 90n^2 - 5n + 6046 \le c_2 n^3$$

$$c_1 \le 3 + \frac{90}{n} - \frac{5}{n^2} + \frac{6046}{n^3} \le c_2$$

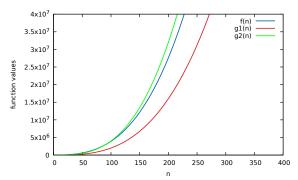

Try
$$c_1 = 2$$
; $c_2 = 4$; $n_0 = 100$; $\Rightarrow f_{div}(n_0) = 3.906546$

Intuitively:

- ▶ set c₁ to a value smaller than the coefficient of the highest-order term
- ▶ and c₂ to a value that is slight larger

ADS Spring 2020 7/23

Plotting Functions Using Gnuplot

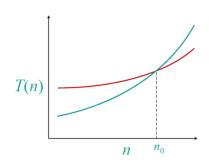

$$f(n) = 3n^3 + 90n^2 - 5n + 6046$$

 $g1(n) = 2n^3$
 $g2(n) = 4n^3$
Gnuplot script

ロ > 4回 > 4 き > 4 き > き め Q (や

Asymptotic Performance

- ▶ When n gets large enough, a $\Theta(n^2)$ algorithm always beats a $\Theta(n^3)$ algorithm
- ► Informal notion:
 - throw away lower-order terms
 - ignore the leading coefficient of the highest-order term

$$3n^3 + 90n^2 - 5n + 6046 = \Theta(n^3)$$

ADS Spring 2020 9 / 23

Asymptotic Analysis

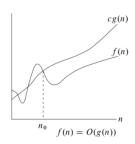

- We should not ignore asymptotically slower algorithms
- Real-world design situations often call for a careful balancing of engineering objectives
- Asymptotic analysis is a useful tool to help to structure our thinking

Asymptotically Upper Bound: O-Notation

For a given asymptotically non-negative function g(n), we define $O(g(n)) = \{f(n) | \exists \text{ positive constants } c \text{ and } n_0, \\ \text{such that } 0 \le f(n) \le cg(n), \forall n \ge n_0 \}$

Example:

We say that f(n) is polynomially bounded if $f(n) = O(n^k)$ for some constant k

Examples

►
$$f(n) = 3n^3 + 90n^2 - 5n + 6046$$

 $\implies f(n) = O(n^3)$

►
$$f(n) = n$$

⇒ $f(n) = O(n^3)$???
⇒ $f(n) = O(n^2)$???
⇒ $f(n) = O(n)$ also true

Asymptotically Lower Bound: Ω -Notation

For a given asymptotically non-negative function g(n), we define $\Omega(g(n)) = \{f(n) | \exists \text{ positive constants } c \text{ and } n_0, \text{ such that } 0 \le cg(n) \le f(n), \forall n \ge n_0 \}$

For tight bounds, we get $\Theta(g(n)) = O(g(n)) \cap \Omega(g(n))$

Non-tight Upper Bound: o-Notation

For a given asymptotically non-negative function g(n), we define $o(g(n)) = \{f(n) | \text{ for any constant } c > 0, \exists n_0 > 0, \\ \text{ such that } 0 \le f(n) < cg(n), \forall n \ge n_0 \}$

$$f(n) = o(g(n))$$
 implies $\lim_{n \to \infty} \frac{f(n)}{g(n)} = 0$

ADS Spring 2020 14 / 23

Examples

▶
$$2n = o(n^2)$$

►
$$2n^2 \neq o(n^2)$$
 ???

▶
$$n^b = o(a^n)$$
 for $a > 1$

Non-tight Lower Bound: ω -Notation

For a given asymptotically non-negative function g(n), we define $f(n) \in \omega(g(n))$ iff $g(n) \in o(f(n))$

$$f(n) = \omega(g(n))$$
 implies $\lim_{n \to \infty} \frac{f(n)}{g(n)} = \infty$

ADS Spring 2020 16 / 23

Asymptotic Analysis: Computation with Limits

$f \in o(g)$	$\lim_{n\to\infty}\frac{f(n)}{g(n)}=0$
$f \in O(g)$	$\lim_{n\to\infty}\frac{f(n)}{g(n)}<\infty$
$f\in\Omega(g)$	$\lim_{n\to\infty}\frac{f(n)}{g(n)}>0$
$f \in \Theta(g)$	$0<\lim_{n\to\infty}\frac{f(n)}{g(n)}<\infty$
$f \in \omega(g)$	$ \lim_{n\to\infty}\frac{f(n)}{g(n)}=\infty $

Asymptotic Analysis of Insertion Sort (1)

```
INSERTION-SORT(A, n)
                                                                     times
                                                               cost
 for j = 2 to n
                                                                     n
                                                               C_1
      kev = A[i]
                                                               c_2 \quad n-1
      // Insert A[j] into the sorted sequence A[1...j-1].
                                                               0 n-1
                                                               c_4 = n - 1
      i = i - 1
                                                               c_5 \qquad \sum_{i=2}^n t_i
      while i > 0 and A[i] > key
          A[i + 1] = A[i]
                                                               c_6 \sum_{i=2}^{n} (t_i - 1)
          i = i - 1
                                                               c_7 \qquad \sum_{i=2}^n (t_i - 1)
      A[i+1] = kev
```

- $ightharpoonup c_k$ is the number of steps a computer needs to perform instruction k once (e.g., a Random Access Machine)
- $ightharpoonup t_j$ is the number of times the while loop is executed in the for iteration j

Asymptotic Analysis of Insertion Sort (2)

- Best case: Input series is ordered.
- ▶ Then, $t_i = 1$.
- $T(n) = \Theta(n)$

Asymptotic Analysis of Insertion Sort (3)

- ▶ Worst case: Input series was ordered in reverse.
- ▶ Then, $t_i = j$.
- With the arithmetic series

$$\sum_{k=1}^{n} k = \frac{n(n+1)}{2}$$

the worst-case asymptotic complexity is

$$T(n) = \sum_{j=2}^{n} \Theta(j) = \Theta(n^2)$$

Asymptotic Analysis of Insertion Sort (4)

► Average case:

All permutations are equally likely.

- ▶ Then, t_j is expected to be $\frac{j}{2}$ on average.
- ▶ Hence, the average-case asymptotic complexity is

$$T(n) = \sum_{i=2}^{n} \Theta\left(\frac{j}{2}\right) == \Theta(n^2)$$

Asymptotic Analysis of Insertion Sort (5)

- ▶ Is Insertion Sort fast?
- ightharpoonup For small n, it is moderately fast.
- ▶ For large *n*, it is slow.

Summary: Asymptotic Analysis

- ► O-notation Asymptotically upper bound
- Ω-notation Asymptotically lower bound
- Θ-notation Asymptotically tight bound
- o-notation Non-tight upper bound
- ightharpoonup ω -notation Non-tight lower bound
- ▶ $f(n) \in O(g(n))$ is like $a \le b$,
- $f(n) \in \Omega(g(n))$ is like $a \ge b$,
- ▶ $f(n) \in \Theta(g(n))$ is like a = b,
- $f(n) \in o(g(n))$ is like a < b,
- $f(n) \in \omega(g(n))$ is like a > b.
